Abstart

Aim of the study The main question of this study is whether there is a specific relation between Dark Triad personality traits and proactive and reactive aggression in adolescents between 14 and 19 years old. Design The present study is a cross-sectional correlational study. Methods There were 62 participants in the study, these participants were aged between 14 and 19 years and were all students of a high school in Maastricht. Both boys (n = 22) and girls (n = 40) participated in the study. To answer the main question, the participants of the study completed two questionnaires. First, they completed the Dirty Dozen for Youths (DD-Y), a questionnaire to measure the Dark Triad personality traits. Second, they completed the Child Rating scale for Aggression (CRA), a questionnaire to measure proactive and reactive aggression. Results There was no significant difference between boys and girls on the aggression questionnaire, but there was a significant difference between boys and girls on the subscales psychopathy and Machiavellianism. There was no difference between the participants from different educational levels and there was no relation between age and the different subscales. To find out if the personality trait of the Dark Triad were unique predictors of general aggression, reactive aggression and proactive aggression, a multiple regression analysis was carried out. It was found that Machiavellianism is a unique predictor for general aggression, proactive aggression and reactive aggression and that psychopathy is a unique predictor for aggression in general. Conclusion Because Machiavellianism and psychopathy have proven to be unique predictors of aggression and Machiavellianism is even a specific predictor of proactive and reactive aggression, an intervention to prevent/reduce the development of aggression may be designed. In this way, it can be prevented that the development of the child is disturbed by aggressive behavior. Further research into the role of Machiavellianism in the development of aggression is recommended.
Keywords
Agression, machiavellisme, narcissism, proactive agression, psychopathy, reactive agression.

Introduction
Aggression is a big problem in society. Especially aggression in youth is regularly in the news. In fact, for no less than 5% of students in the Netherlands there is reason for concern because of their physical aggressive behavior. Aggressive behavior in children has not only negative consequences for the environment of the aggressive child, but also for the aggressive child. For example, aggressive children are at greater risk of getting a depression.

Aggressive behavior takes different forms and can manifest itself physically, verbally and socially. In addition to the various forms of aggression, aggression can be divided into two functions: proactive and reactive aggression. Proactive aggression is defined as an unprovoked, aversive behavior intended to harm, dominate, or coerce another person. Reactive aggression is a defensive response to a perceived threat, fear, or provocation. Previous research has shown that personality plays an important role in the development of aggressive behavior. This study focused on three undesirable personality traits. The Dark Triad is a term used to describe these constellation of three socially undesirable personality traits: narcissism, psychopathy, and Machiavellianism.

Narcissism is characterized by an exaggerated sense of superiority, greatness and self-esteem. Individuals who score high on narcissistic traits are further described as hostile, hypersensitive to criticism and a lack of empathy. Individuals with high levels of Machiavellianism think that people are weak and unreliable, are cynical about humanity and have a lack of emotion. In addition, these people are very manipulative. The last Dark Triad personality trait, psychopathy, is characterized by defects in interpersonal, affective and behavioral domains. At the interpersonal level, people with psychopathic traits are superficially charming, narcissistic and manipulative. On the emotional level, they are heartless, emotionless and lack empathy and remorse. Behaviorally, people with psychopathic tendencies are impulsive, irresponsible and prone to antisocial and thrill-seeking behavior. Although these personality traits are overlapping, they are still different constructs.
The main question of this study is whether there is a specific relation between Dark Triad personality traits and proactive and reactive aggression in adolescents between 14 and 19 years old. It is expected that a relationship does exist between general aggression, proactive aggression and reactive aggression and the Dark Triad personality traits and that, as in previous studies, two out of three dark triad personality traits, namely narcissism and psychopathy, correlate with aggression\(^6,7\).

**Methods**

**Participants**

Sixty-two participants were included in this study, these participants were aged between 14 and 19 years (\(M = 15.8, SD = 1.35\)) and were all students of a high school in Maastricht. Both boys (n = 22) and girls (n = 40) participated in the study and the students were spread over four levels of education.

**Design and measures**

The present study is a cross-sectional correlational study. To answer the main question of the present study, the participants of the study completed two questionnaires. First, they completed the Dirty Dozen for Youths (DD-Y), this is a questionnaire to measure the Dark Triad personality traits. The Dirty Dozen that was used in this study has proven to be reliable and valid in previous research\(^8\). The DD-Y is derived from the adult version which has been developed by Jonason and Webster \(^9\). The questionnaire consists of 12 5-point Likert items and three subscales (narcissism, Machiavellianism and psychopathy). All three subscales include four 5-point Likert items.

Second, the participants completed the child rating scale for aggression (CRA), this is a questionnaire to measure proactive and reactive aggression. The CRA is a self-report version of the Teacher Rating Scale for Aggression (TRA) by Brown et al.\(^3\), and has proven to be reliable and valid in previous research\(^10\). The questionnaire consists of 21 5-point Likert items and two subscales (proactive aggression and reactive aggression). The proactive aggression subscale consists of 10 5-point Likert items and the reactive aggression subscale consists of six 5-point Likert items. The other five 5-point Likert items are not classified.

**Statistical analysis**

All data was analyzed using SPSS. To examine whether there was a significant difference between the scores of boys and girls on the questionnaires, an independent samples
t-test was performed. An independent samples t-test was also performed to see if there was a significant difference between the several levels of education. Pearson correlations were calculated to examine whether there was a link between age and the scores on the different subscales of the questionnaires. Pearson correlations were then calculated to find out if there might be a relationship between the Dark Triad personality traits and aggression and proactive and reactive aggression. Relevant variables were then added to a regression model. To examine which personality traits of the Dark Triad were unique predictors of aggression, a multiple regression analysis was performed. The personality traits of the Dark Triad (narcissism, Machiavellianism and psychopathy) were the independent variables in the model and general aggression, proactive aggression and reactive aggression were the dependent variables in the model.

Results

General results
As shown in table 1, boys and girls scored significantly different on the DD-Y, boys scored significantly higher on the questionnaire than girls. Also on the subscales psychopathy and Machiavellianism there was a significant difference between boys and girls, the boys scored higher than the girls again.

</table>

Note: DD-Y = Dirty Dozen for Youths, CRA = Child Rating Scale for Aggression. Significant gender difference at p < .01.
No significant correlation was found between age and the subscales proactive aggression \( (r = -.01, p = ns) \), reactive aggression \( (r = .00, p = ns) \), narcissism \( (r = .05, p = ns) \), Machiavellianism \( (r = .14, p = ns) \) and psychopathy \( (r = -.05, p = ns) \). Because only one participant of the VMBO and one participant of the practical education participated in the study, they were excluded here. No significant difference between HAVO and VWO was found, neither with regard to CRA nor DD-Y (CRA \( t(56) = .02, p = ns \) and DD-Y \( t(56) = .09, p = ns \)) and the subscales of the CRA (proactive aggression \( t(55) = .42, p = ns \) and reactive aggression \( t(58) = .08, p = ns \)) and the DD-Y (narcissism \( t(57) = 1.39, p = ns \), Machiavellianism \( t(57) = .74, p = ns \) and psychopathy \( t(57) = .38, p = ns \)).

Relationship between Dark Triad personality traits and aggression
The Dark Triad personality traits correlated positively with aggression \( (r_s \text{ between } .51 \text{ and } .73, p < .01) \). A positive correlation was also found between the subscales of the DD-Y and the subscales of the CRA \( (r_s \text{ between } .41 \text{ and } .70, p < .01) \). Of the Dark Triad personality traits, Machiavellianism shows the strongest positive correlation with total aggression \( (r = .73, p < .01) \), proactive aggression \( (r = .69, p < .01) \), and reactive aggression \( (r = .70, p < .01) \).

Unique predictors of aggression
Narcissism, Machiavellianism and psychopathy were added to the regression model because all Dark Triad personality traits significantly correlated with overall aggression, proactive aggression and reactive aggression. The regression model with overall aggression as the dependent variable and narcissism, Machiavellianism and psychopathy as independent variables was significant, \( F(3, 55) = 26.08, p < .001 \). In Table 3 is shown that Machiavellianism is the strongest predictor of general aggression. In table 3 can also be seen that narcissism is not a unique predictor of general aggression.

The regression model with proactive aggression as the dependent variable and narcissism, Machiavellianism and psychopathy as independent variables is significant, \( F(3, 54) = 19.80, p < .001 \). In Table 3 is shown that Machiavellianism is the only unique predictor of proactive aggression.

The last regression model with reactive aggression as the dependent variable, and narcissism, Machiavellianism and psychopathy as independent variables is also significant, \( F(3, 56) = 18.91, p < .001 \). Machiavellianism turns out to be the only unique predictor of reactive aggression.
By calculating partial correlations it was examined whether the previously demonstrated associations between the dark triad personality traits and aggression, proactive aggression and reactive aggression existed after adjustment for other variables in the dataset. The strength of the correlation drops significantly after adjustment for other variables. After controlling for the influence of other variables, Machiavellism proved to be the only significant correlation with aggression, proactive aggression and reactive aggression (partial $r_i$ between .48 and .46, $p < .001$).

Discussion/Conclusion

In contrast to the study conducted by Barry et al., the current study showed that narcissism is not a unique predictor of proactive and reactive aggression or aggression in general. The relationship between narcissism and aggression even proved to be the weakest in the current study. This would mean that there are no immediate concerns needed about the development of aggressive behavior in children who exhibit narcissistic traits.

It was also found that psychopathy is not a unique predictor of specific proactive aggression or reactive aggression. However, it was found that psychopathy is a unique
predictor of aggression in general. This would mean that there are concerns needed about
the development of aggressive behavior in children who exhibit psychopathic traits.
However, this is not in line with the research that was previously done by Cima and Raine
\(^7\) where psychopathy was correlated with proactive aggression.

The only unique predictor of general aggression, proactive aggression and reactive
aggression found in the present study is Machiavellianism. This would mean that there
are concerns needed about the development of aggressive behavior in children who
exhibit traits of Machiavellianism. This is not in line with the fairly recent study of Lau
and Marsee \(^3\) nor with the study of Loftus and Glenwick \(^11\). In these studies, no correlation
between Machiavellianism and aggression was found.

From the results of the present study we can indeed conclude that there is a relationship
between some of the Dark Triad personality traits and general aggression, proactive
aggression and reactive aggression. However, the relations that are found in this study are
not in line with the existing literature. These different results may be related to a number
of shortcomings in the current study. The main limitation is probably the small size of the
study population, the study population is too small to generalize to the real population.
That the participants were all non-clinical adolescents may also be seen as a limitation.
A final limitation of the present study is that only self-report has been used to measure
aggression and the Dark Triad personality traits, in this way there is a greater chance of
socially desirable answers. If using multiple informants (e.g., teachers and parents) the
likelihood of socially desirable answers is smaller.

If Machiavellianism and narcissism turn out to be unique predictors of aggression, and
if Machiavellianism really turns out to be a specific predictor of proactive and reactive
aggression, there may possibly be designed an intervention to prevent/reduce the
development of aggression. In this way, it can be prevented that the development of
the child is disturbed by aggressive behavior. However, further research into the role of
Machiavellianism in the development of aggression is recommended.

Role of the student
Stephanie van Lier was an undergraduate student working under the supervision of Cor
Meesters when the research in this report was performed. The topic was proposed by the
supervisor. The processing of the results as well as the formulation of the conclusions and
the writing were done by the student.
